X-ray fluorescence

Fluorescence - absorption of radiation of a specific energy results in the re-emission of radiation of a different energy (generally lower).

- X-ray photons knock out inner orbital electrons
- Outer orbital electrons move into vacancy
- Fluorescence emitted at element-specific wavelength

PXRF

Portable X-ray fluorescence environmental analyzer

Innov-X (Olympus) Delta Standard model

- Good sensitivity
- Highly recommended
- Good customer service
- No software needed
 - Needed only with workstation

Innov-X Delta Standard Model

Element Limit of Detection

Rb, Sr, Zr, Mo	1 ppm
As, Se, Br	1 to 3 ppm
Pb, Hg	2 to 4 ppm
Zn, Mn, Ga	3 to 5 ppm
Cu, Fe	5 to 7 ppm
Ag, Cd	6 to 8 ppm
Cr	5 to 10 ppm
Ti, V	7 to 15 ppm
Sn, Sb	12 to 15 ppm
Co, Ni, Ba	10 to 20 ppm
Ca	20 to 30 ppm
K	30 to 50 ppm
S	100 to 250 ppm
P	500 to 700 ppm

OLYMPUS
Your Vision, Our Future

HANDHELD XRF ANALYZERS
Limits of Detection

Alloy Analysis:
Elements detected: Magnesium (Mg, Z=12) through
Sulfur (S, Z=16) and Titanium (Ti, Z=22) through
Plutonium (Pu, Z=94).

Please see separate Alloy Analysis LOD Specifications.

Detection limits are a function of testing time, sample matrix and presence of interfering elements.
Detection limits are estimates based on 1.2 minutes test time and detection confidence of 3σ (99.7% confidence).
Interference-free detection limits are intended as guidelines; please contact Olympus Innov-X to discuss your specific application.

Radiation Safety

Maximum exposure

< 1uSv* (10^{-6}) at the trigger ~ < 2mSv annually to the hand
(ICRP max to extremity = 50 mSv for gen. public)

100 uSv per dental X-ray

10 seconds exposure to beam = 550 mSv

*1 sievert = 100 rem = 5.5% chance of developing cancer

Calibration/QA

- Energy calibration check at least twice daily
- A blank (SiO_2) is run every 20 samples
- Calibration verification with reference standards is run at least once daily
 - NIST ref materials → high & med trace metal soils
 - Difference between pXRF measurements and the reference soils should $\leq 20\%$

Sources of error

- Non-homogenous sample
 - Sieve sample
 - Mortar & pestle (EPA method 6200)
- Soil moisture - dilution effect
 - Air dry sample

Workstation

- Office setup
- Emissions contained in chamber
- Need additional software

Onsite screening method

- Grid pattern to cover area of interest
- Auger sample at 2 depths

Lead in Garden Soils

By Dave Pittwell, Assistant Extension Educator

What is lead?

Lead is a soft, grayish-white, naturally occurring metal that has been mined for thousands of years. Early Egyptians, Greeks and Romans used it for water pipes and in ceramic glazes and paint pigments. In the eighteenth century, lead poisoning among Americans and the English was traced to soft soap made with lead. Early bankers and printers were exposed to lead through their daily work activities. Lead was an ingredient in paint for many years because it covered a rough, flaking film when dry. Although the dangers of lead poisoning have been known for almost 2000 years, lead still continues to be used for industrial purposes. It remains in use because of its properties that make it a versatile, durable and economical material.

Where is lead and what are considered to be normal background levels?

Lead is everywhere. It is present in water, soil, our homes, our cars, our food and even in our bodies. In fact, no other contaminant has accumulated in humans to average levels as close to those which are potentially clinically poisonous. In native, undisturbed soils, lead generally ranges from 1 to 60 parts per million. Over the years, human activity has increased the levels of lead in some soils to hazardous levels.

How did soils become contaminated with lead?

Lead contamination and health problems caused by the contamination are associated mostly with mining, smelting and other industrial activities. In New England, lead contamination is primarily due to three sources – lead paint, exhaust from leaded gasoline, and the use of lead arsenate as a pesticide, particularly in old orchards. Use of these products has been phased out, but lead is a persistent pollutant and will remain in the soil for many years indefinitely. Because it is a metal, it will not decompose. Lead can, however, accumulate in plant tissues.

Many homes in New England were built before 1978 when lead was banned from paint for U.S. homes. At the paint age and peeling, it was scraped off, stored in unsightly cans in the paint shop and then falling in the ground. The closer the home, the more likely this

process was repeated over the years. Even rain washing down buildings covered with lead-based paint may carry some lead into the surrounding soil. Unless the soil was physically disturbed, a typical family in contact to soil lead levels being highest closest to the home with the levels decreasing as the distance from the building increases. The U.S. Environmental Protection Agency (EPA) found that the highest soil lead levels were located within the 1- to 3-foot drip line around the home.

Lead was used in gasoline as an anti-knock ingredient. Two forms of lead were used as additives, tetraethyl lead and tetramethyl lead. These were banned in 1991 as a result of the Clean Air Act. By some estimates, hundreds of thousands of pounds of lead found their way into the air each year via vehicle exhausts. Because of the use of lead in gasoline, so many heavily traveled roadways are often found to contain elevated levels of lead.

Sometime in the late 1800's, lead arsenate was introduced as an insecticide for fruit trees. Orchards were a common site across the New England landscape. Many are still in production today. Although use of lead arsenate was discontinued in the 1940's, lead as well as arsenic remains in the soil on these old orchard sites, some of which have been developed and sold as residential properties.

Who is affected by lead?

While lead poisoning knows no age boundaries, most at risk from exposure to lead are children between the ages of six months to six years. This is because they most commonly engage in hand-to-mouth activities through which lead can be ingested. Toys or food can be dropped on contaminated soil and picked up by children who may put this item or their dirty hands in their mouths. Children often engage in physical activities on the ground that may stir up dust, which is then inhaled or ingested. Contaminated soil inadvertently brought into homes on shoes or from home renovations may also be ingested by young children. Older homes may have peeling paint chips that children could ingest.

How does lead affect children and adults?

Lead Contaminated Soil: Minimizing Health Risks

Lead in Our Environment

Lead is a naturally occurring element found in soils at low concentrations. Elevated levels of lead are usually due to contamination. Living systems have no known biological use for lead, and exposure to elevated concentrations of lead can cause human health problems.

Gardening or playing where soils are contaminated with lead can result in toxicity in humans. Lead can be transferred from the soil when inhaled as soil dust or when directly ingested. While few people deliberately eat soil, young children, especially toddlers, are at the greatest risk for accidentally ingesting soil and dust, since they have heightened hand-to-mouth activity. The United States Center for Disease Control and Prevention (CDC) has indicated that lead poisoning is one of the most common, but also preventable, childhood environmental health issues facing our country today. New Jersey law requires physicians to screen all children for elevated blood lead levels.

Specific Health Concerns

Children are more sensitive than adults to lead exposure since their brains and bodies are quickly developing, and can absorb and retain high percentages of lead. Extremely high levels of lead in the blood (80 µg/dL) are rare in this country but can cause coma and death. The consequences of moderate levels of exposure to ingested lead (10 to 40 µg/dL) include neurological damage, lowered IQ, learning disabilities, decreased stature and may be associated with delinquency.

One problem with moderate lead poisoning (10 to 40 µg/dL blood lead) is that the symptoms are not unique to lead exposure and can be mistaken for other illnesses. Children with blood lead levels in this range may develop deficiencies in speech and language processing, attention and classroom performance.

The Centers for Disease Control and Prevention has recognized "that a blood lead of 10 µg/dL did not define a threshold for harmful effect", which means that even blood lead levels less than 10 µg/dL may cause adverse health effects. New Jersey state law requires physicians to screen children between the ages of 12 and 24 months for blood lead levels. Blood levels greater than 20 µg/dL lead to notification of health and human services personnel. Chelation therapy is recommended for blood lead levels greater than 45 µg/dL. Children are not the only ones affected. Lead exposure can cause similar neurological health problems for adults. Fetuses are also at risk, because lead can be transferred from the mother. Nursing mothers can deliver lead through breast milk.

Pollution Sources

Some soils were polluted long ago by lead. Leaded gasoline contained tetraethyl lead as an antiknock agent for many years; this was volatilized in engines and emitted from tailpipes. Lead was deposited along streets and highways until lead use in gasoline was prohibited in the United States, in 1986. Lead from automobile emissions is estimated to have

Healthy Soils, Healthy Communities Metals in Urban Garden Soils

Metals are naturally present in rock, soil, and other materials. They are also used in manufactured (anthropogenic) materials, and human activity can increase the levels of metals in soil. Urban soils often have higher levels of metals than rural soils because they have been affected more by human activity. Gardening in urban soils may increase your exposure to metals if you swallow or breathe in soil particles or eat food raised in or on the soil.

What metals can be found in urban gardens?

The table on this page lists several metals commonly found in urban garden soils, along with guidance values developed to protect human health, and ranges of "background" levels typically found in rural and urban soils in New York State (NYS) and New York City (NYC).

The following pages provide some basic information for gardeners about each of these metals: where they come from (both natural and anthropogenic sources), how they behave in soil, considerations for human and plant health, and what gardeners can do to help reduce exposure to metals in garden soils.

What levels of metals are acceptable in garden soils?

There are no standards protective of public health specifically for metals in garden soils in NYS, but there are guidance values developed for other purposes that gardeners can consider. The guidance values in the table on this page are residential soil cleanup objectives developed by the NYS Department of Environmental Conservation and the NYS Department of Health for the NYS environmental remediation programs (see References, p. 9). These values were developed to consider residential exposures, including gardening. However, they assume that you live on the property with the soil, and that you are exposed in some way every day and over a lifetime. Exposure to metals in soils for an urban gardener may be less than this.

The guidance values also generally assume that metals are in one of the most toxic and available chemical forms, which is not always the case with metals in garden soil. Metals can be present in soil in different chemical forms. The behavior of metals in the environment, tendency to be taken up by plants, toxicity to plants and potential for health effects of human exposure to these metals depend on their chemical form. For example, some forms of metals can readily dissolve in water (soluble) and therefore can enter plants or the human body more easily than forms that cannot easily dissolve (insoluble). Human and plant toxicity depend upon the amount of metal that enters the body or plant.

Should I be concerned about exposure to metals in my garden soil?

Certain metals are essential in small amounts in the diet for good health, but eating or drinking large amounts of them can cause health effects. Other metals can cause health effects even in small amounts. Lead can pose a particular health concern, especially for young children. The likelihood that health effects will occur depends

Metals commonly found in urban garden soils: Guidance values and background levels^a

Metal	Level in soil (parts per million [ppm])		
	Guidance Value Protective of Public Health	NYS Rural Background Level	NYC Urban Background Level
Arsenic	16	< 0.2 - 12	4.1 - 26
